

## Matching

A matching in a graph  $G$  is a set  $M$  of edges such that no two edges <sup>of  $M$</sup>  are adjacent.

If  $M$  is a matching then the two ends of each edge of  $M$  are said to be matched under  $M$ . ~~Each vertex~~

~~Each vertex~~

Each vertex incident with an edge of  $M$  is said to be covered by  $M$ .

A Perfect matching is the one which covers every vertex of  $G$ . A graph  $G$  is called matchable if it has a perfect matching.

A matching  $M$  in  $G$  is a maximum matching if  $G$  contains no matching more than  $|M|$  edges.

The number of edges in a maximum matching of  $G$  is called the matching number and we denote it by  $\alpha(G)$ .

A maximal matching is a matching of  $G$  which cannot be extended to a larger matching.

Ex

Perfect matching

Let  $M_1$  and  $M_2$  be matchings of  $G$ . Then the symmetric difference of  $M_1$  and  $M_2$ , denoted by  $M_1 \Delta M_2$ , defined as a subgraph  $H$  of  $G$  whose components are paths or even cycles of  $G$  in which the edges alternate between  $M_1$  and  $M_2$ .

Let  $M$  be a matching in  $G$ . An  $M$ -alternating path or cycle in  $G$  is a path or cycle whose edges are alternating in  $M$  and  $E \setminus M$ .

An  $M$ -alternating path might or might not start or end with edges from  $M$ . If neither its origin nor its terminus is covered by  $M$ , then the path is called an  $M$ -augmenting path.

Th<sup>m</sup> A matching  $M$  of  $G$  is maximum if and only if  $G$  has no  $M$ -augmenting path.

Proof Assume that  $M$  is maximum. If  $G$  has an  $M$ -augmenting path  $P: v_0 v_1 \dots v_{2n+1}$  in which the edges alternate between  $E \setminus M$  and  $M$ , then  $P$  has one edge of  $E \setminus M$  more than that of  $M$ . Define  $M' = M \cup \{v_0 v_1, v_2 v_3, \dots, v_{2n} v_{2n+1}\} \setminus \{v_1 v_2, \dots, v_{2n-1} v_{2n}\}$ . Clearly  $M'$  is a matching of  $G$  with  $|M'| = |M| + 1$ , which is a contradiction, since  $M$  is a maximum matching of  $G$ .

Conversely assume that  $G$  has no  $M$ -augmenting path. Suppose  $M$  is not a maximum matching. Then there exists a matching  $M'$  of  $G$  with  $|M'| > |M|$ . Let  $H$  be the edge subgraph  $G[M \Delta M']$ . Then the components of  $H$  are paths or even cycles in which the edges alternate between  $M$  and  $M'$ . Since  $|M'| > |M|$ , at least one of the components of  $H$  must start and end with edges of  $M'$ . But then such a path is an  $M$ -augmenting path of  $G$ , contradicting the assumption.

A factor of  $G$  is a spanning subgraph of  $G$ .

A  $k$ -factor of  $G$  is a factor of  $G$  that is  $k$ -regular. Thus a 1-factor of  $G$  is a perfect matching of  $G$ . A 2-factor of  $G$  is a factor of  $G$  that is a disjoint union of cycles of  $G$ .

A graph  $G$  is  $k$ -factorable if  $G$  is an edge-disjoint union of  $k$ -factors of  $G$ .

Ex

$G_1$

- 1-factorable

$G_2$

- 2-factorable

$G_3$

Neither a 1-factor nor a 2-factor.

## Matching in a bipartite graph

For a subset  $S$  of  $V(G)$ ,  $N(S)$  denotes the neighbour set of  $S$ , i.e. the set of all vertices each of which is adjacent to at least one vertex.

### Th<sup>m</sup> (Hall)

Let  $G$  be a bipartite graph with bipartition  $(X, Y)$ . Then  $G$  has a matching that covers all the vertices of  $X$  if and only if  $|N(S)| \geq |S|$  for every subset  $S$  of  $X$ .

Proof If  $G$  has a matching that saturates all the vertices of  $X$ , then each vertex of  $X$  is matched to a distinct vertex of  $Y$ . Hence,  $|N(S)| \geq |S|$  for every  $S \subseteq X$ .

Conversely, assume that  $|N(S)| \geq |S|$  for all  $S \subseteq X$ .

Suppose that  $G$  has no matching that saturates all the vertices of  $X$ . Let  $M$  be a maximum matching of  $G$ . As  $M$  does not ~~saturate~~ saturate all the vertices of  $X$ , there exists a vertex  $x_0 \in X$  that is  $M$ -unsaturated. Let  $Z$  denote the set of all vertices of  $G$  connected to  $x_0$  by  $M$ -alternating path.

Since  $M$  is a maximum matching, so  $G$  has no  $M$ -augmenting path.

As  $x_0$  is  $M$ -unsaturated, this implies that  $x_0$  is the only vertex of  $Z$  that is  $M$ -unsaturated.

Let  $A = Z \cap X$  and  $B = Z \cap Y$ . Then the vertices of  $A \setminus \{x_0\}$  get matched under  $M$  to the vertices of  $B$  and  $N(A) = B$ . Thus since  $|B| = |A| - 1$ ,  $|N(A)| = |B| = |A| - 1 < |A|$ , a contradiction to our assumption.

Th<sup>m</sup> A  $K(k, 1)$ -regular bipartite graph is 1-factorable.

Proof Let  $G$  be  $k$ -regular with bipartition  $(X, Y)$ .

The  $E(x) =$  the set of edges incident to the vertices of  $x =$  the set of edges incident to the vertices of  $y$ . Hence  $k|x| = E(x) = k|y| \Rightarrow |x| = |y|$ .

If  $S \subseteq X$ , then  $N(S) \subseteq Y$  and  $N(N(S)) \supseteq S$ .

Let  $E_1$  and  $E_2$  be the set of edges of  $G$  incident to  $S$  and  $N(S)$ , respectively. Then

$E_1 \subseteq E_2$ ,  $|E_1| = k|S|$  and  $E_2 = k|N(S)|$ . Hence

$|N(S)| \geq |S|$  as  $|E_2| \geq |E_1|$ . So by Hall's Theorem

$G$  has a matching that saturates all the vertices of  $X$ ; i.e.  $G$  has a perfect matching. Deletion of the edges of  $M$  from  $G$  results in a  $(k-1)$  regular bipartite graph. Repeated application of the above argument shows that  $G$  is 1-factorable.
